Core Concepts and Theoretical Foundations

To appreciate Goodman's approach, it is essential to understand the central concepts that underpin Fourier optics.

Wave Propagation and Diffraction

At its core, Fourier optics models how light waves propagate through space and interact with

objects:

- Huygens-Fresnel Principle: Every point on a wavefront acts as a secondary source of spherical wavelets.
- Fresnel and Fraunhofer Diffraction: Approximate models that describe how light diffracts through apertures and lenses under near-field and far-field conditions, respectively.

Goodman meticulously derives these principles, illustrating how diffraction patterns can be represented as Fourier transforms of the aperture functions. This approach simplifies complex wave interactions into manageable mathematical operations.

Fourier Transform in Optics

The linchpin of Fourier optics is the Fourier transform, which converts a spatial domain function into its frequency domain equivalent:

- Mathematical Definition:

$\mathcal{F}\{f(x)\} = \int_{-\infty}^{\infty} f(x) e^{-i 2\pi u x} dx$

$$\mathcal{F}\{f(x)\} = \int_{-\infty}^{\infty} f(x) e^{-i 2\pi u x} dx$$

- Physical Interpretation: Spatial features correspond to specific frequency components; analyzing these components reveals how optical systems manipulate images and wavefronts.

Goodman emphasizes the physical significance of Fourier transforms, using visualizations and examples that relate mathematical operations to measurable optical phenomena.

Transfer Functions and System Analysis

Fourier optics provides tools to analyze optical systems as linear, shift-invariant systems characterized by their transfer functions:

- Optical Transfer Function (OTF): Describes how different spatial frequencies are transmitted or attenuated.

- Point Spread Function (PSF): The system's response to a point source, obtainable via inverse Fourier transform of the OTF.
