WAG reservoir simulation using ECLIPSE has become an essential component of modern reservoir management. As the oil and gas industry shifts towards more sophisticated and accurate modeling techniques, reservoir engineers increasingly rely on advanced simulation tools to optimize recovery strategies. WAG, or Water Alternating Gas, injection is a widely used EOR (Enhanced Oil Recovery) method that involves cyclically injecting water and gas into the reservoir to maximize hydrocarbon extraction. When combined with powerful simulation platforms like ECLIPSE, WAG modeling provides invaluable insights into reservoir behavior, aiding engineers in decision-making processes that can significantly impact project economics and recovery efficiency.

In this article, we delve into the fundamentals of WAG reservoir simulation using ECLIPSE, exploring the underlying principles, steps for setup, best practices, and interpretation of results. Whether you are a seasoned reservoir engineer or a student venturing into EOR modeling, this guide aims to demystify the process and provide practical knowledge for effective simulation.

Understanding WAG and Its Role in Reservoir Management

What is WAG?

Water Alternating Gas (WAG) injection is an enhanced oil recovery technique designed to improve sweep efficiency and reduce fingering issues associated with gas injection. The process involves cyclically injecting water and gas into the same injection wellbore, followed by production phases. Typical WAG cycles might be structured as:

- Inject water for a specified period or volume
